Standard Reference Material® 3190

Aqueous Electrolytic Conductivity

Lot No. 042203

This Standard Reference Material (SRM) is intended primarily for use in electrolytic conductivity measurement as a calibration standard or control sample. As a calibration standard, it can be used to determine the conductivity cell constant. One unit of SRM 3190 consists of one 500-milliliter bottle filled with a solution of dilute hydrochloric acid (HCl) in deionized water in equilibrium with atmospheric carbon dioxide.

SRM 3190 was prepared gravimetrically using deionized water that was filtered through a 0.22-micrometer filter. The initial electrolytic conductivity of this water was less than 0.2 μS/cm. The solution was dispensed into high-density polyethylene (Nalgene®)[1] bottles, the caps sealed in beeswax, and the entire bottle sealed in an aluminized bag. The certified electrolytic conductivity and its uncertainty given below were established through determinations with a conductivity cell immersed in a constant temperature oil bath and using a Jones bridge with a null detector. The conductivity bridge and electronics are described in references 1and 2.

The certified value given below is based on equilibrium conditions, and the solution should **NOT** be degassed before use.

Electrolytic Conductivity at 25.000 °C: 25.70 μS/cm ± 0.96 μS/cm

The uncertainty in the certified value, U = 0.96 μS/cm, is calculated as

$$U = 2.0\, u_c$$

where u_c is the combined standard uncertainty calculated according to the ISO/Guides [3]. The value of u_c represents, at the level of one standard deviation, the effect of the uncertainty component associated with the instability of the batch (all other uncertainty components are insignificant). The value of u_c has been multiplied by 2.0, which is the coverage factor corresponding to approximately 95 % confidence based on greater than 1000 effective degrees of freedom.

Expiration of Certification: The certification of **SRM 3190 Lot No. 042203** is valid, within the measurement uncertainty specified, until **23 March 2005**, provided the SRM is handled in accordance with instructions given in this certificate (see "Instructions for Use"). This certification is nullified if the SRM is damaged, contaminated, or otherwise modified.

This SRM was prepared and analyzed by R.H. Shreiner of the NIST Analytical Chemistry Division.

Certificate Issue Date: 10 June 2004

Robert L. Watters, Jr., Acting Chief
Measurement Services Division

[1]Certain commercial equipment, instruments, or materials are identified in this certificate in order to specify adequately the experimental procedure. Such identification does not imply recommendation or endorsement by the National Institute of Standards and Technology, nor does it imply that the materials or equipment identified are necessarily the best available for the purpose.

Statistical consultation was provided by W.F. Guthrie of the NIST Statistical Engineering Division.

The support aspects involved with the issuance of this SRM were coordinated through the NIST Standard Reference Materials Program by C.S. Davis of the Measurement Services Division.

Maintenance of Certification: NIST will monitor representative solutions from this SRM lot over the period of its certification. If substantive changes occur that affect the certification before the expiration of certification, NIST will notify the purchaser. Registration (see attached sheet) will facilitate notification.

Conductivity is strongly influenced by temperature, and for this solution, the temperature coefficient at 25 °C is approximately 2 % per °C [4]. The certified value and its uncertainty were determined with the temperature at 25.000 °C ± 0.004 °C.

INSTRUCTIONS FOR USE

After the bottle has been removed from the aluminized bag, instability will occur at an accelerated rate resulting in a gradual increase in the conductivity. Thus, the SRM should be used as soon as the bottle is removed from the aluminized bag. Storage of a partially used SRM bottle is not recommended.
